Deep Dive into Circuit Design for AM Simulation in Multisim

Message and Carrier Signal Generation

For accurate AM simulations, selecting appropriate waveforms and parameters is critical:

- Message Signal:** Typically a low-frequency sine wave (e.g., 1 kHz) with variable amplitude.
- Carrier Signal:** A high-frequency sine wave (e.g., 100 kHz to 1 MHz).

In Multisim: Use the AC Voltage Source or Function Generator blocks for both message and carrier signals. Set frequencies and amplitudes as per experimental or instructional requirements.

Implementing the Modulator Circuit

The core of AM simulation involves multiplying the message and carrier signals:

- Operational Amplifier-Based Multiplier:** For advanced learners, circuits utilizing op-amps and diodes can mimic multiplier behavior but are less straightforward.

Typical schematic: Connect message signal to one input of the multiplier. Connect carrier signal to the other input. The output represents the amplitude-modulated wave.

Adjusting Modulation Index

The modulation index (m) determines the extent of amplitude variation: $m = \frac{A_m}{A_c}$, where A_m is message amplitude and A_c is carrier amplitude. In simulation, vary message amplitude or carrier amplitude to achieve desired m .

Monitoring the modulated waveform allows students to observe how the modulation index influences the envelope shape.
